For my event, the user will be interacting with the feature form, specifically the submit button. The event that triggers the function is a click event, when a user clicks on the submit button, a function handleSubmit is called. This function prevents the default behavior of the form element and displays a message stating that the user responses were successfully recorded. It also resets the form in the event a user wants to submit another feature request.

Event: *click* submit button in form

FUNCTION: handleSubmit()
Display "Your responses were successfully recorded.'

Show 'Your responses were successfully recorded.'
